Summary. The electrohydraulic drive with volume regulation is considered.
A volume pump with adjustable feed, assistive devices and executive hydraulic motor volume type are included in power part of the drive. Axial piston pump, the feed of which is controlled by varying the inclination angle of the cylinder block or change the angle of the swash spacer is used in the hydraulic drive. Hydraulic axial piston or radial-piston motor is used as an executive. Auxiliary devices: flap, filter, pump and tank system for feeding hydraulic fluid power part of the drive are set in the hydraulic drive. From extremely high-pressure pipelines of hydraulic drive is protected by two safety flap. The auxiliary pump injection line also has a safety flap which protects the pump from the pressure increase when the filter is clogged. In the development of a mathematical model the following assumptions: an asynchronous motor rotates the pump shaft with an angular velocity, whose value does not depend on the power developed by the pump; when the hydraulic drive pressure in the pipes do not reach values at which the safety flap open; line pressure before makeup flap is kept constant; force to overcome the hydraulic motor in the control of the object represented by the sum of the moments of action given to the shaft motor inertia load, positional load and hydraulic friction; pipes are made so short that it was possible to them to neglect the inertia of the fluid and pressure losses due to friction resistance are made.
The mathematical model of the dynamic characteristics for the power unit of the automatic electrohydraulic drive with volume regulation is developed. A block diagram of the control signal transmission is represented. Transfer function of the drives received.
Key words: mathematical model, pump, motor, pressure, flow, volume control, a block diagram, transfer function.

INTRODUCTION

Modern technologies of materials processing, plastic molding machine designs placing ever-increasing demands on the technical and functional characteristics of machine tools and special process equipment. The quality of the products for machining, forming, plastic molding depends on the feasibility of optimal laws of motion of blades, precision control of their movements, stability, speed with variable load. Therefore important the scientific and technical task is to improve the accuracy and extend the functionality of machines and equipment for processing materials.

Achievement of any of the kinematics of the working body, the possibility of program implementation optimal laws of motion provided by the use of automatic hydraulic transmission and, in particular, auto electrohydraulic drive (EHD) with volume control in equipment capacity exceeding 8 kW[1-3]. However, there are currently no generic mathematical model of the work processes that take place in the drive, there is no generally accepted methods for calculating EHD adapted to drive machine tools and special equipment for material processing, enables the assessment and selection of drive components and devices, to predict its static and dynamic characteristics.
The power part of the electrohydraulic servo drive (EHD) includes a positive displacement pump with adjustable pitch, and accessories, the executive hydraulic motor displacement type. The most widely used in servo-hydraulic actuator has axial-piston pumps, which flow is regulated by a change in the angle of the cylinder, or changing the angle of inclination of the puck[4-7]. As actuation hydraulic cylinders typically used with linear transmission output link, hydraulic cylinders with a rotary motion of the output link and axial piston and radial piston motors. Auxiliary devices include valves, filter, pump and tank system of feeding with work fluid of hydraulic power unit.
The aim of this work is to develop mathematical models of dynamic characteristics of the power unit of the automatic electrohydraulic drive with volume control and obtaining the transfer function of the drive by the control signal.

OBJECTS AND PROBLEMS

The aim of this work is to develop mathematical models of dynamic characteristics of the power unit for the automatic electrohydraulic drive with volume control and obtaining the transfer function of the drive by the control signal.

THE MAIN SECTION

At Fig. 1 a schematic diagram of a typical power unit of the drive with volume control containing two axial
piston hydraulic machines[2, 11-13]: the main hydraulic pump 2 and motor 5 is presented. The pump shaft is driven by an asynchronous motor 1. Pump capacity is controlled by varying the angle of the cylinder block (or angle washer) with the 3, which can also be power, consisting of cylinder and valve. The pipe is connected to motor with two pipelines 4. Motor shaft via a gear 6 is connected to the governing board 7. For the leakages of fluid is an auxiliary pump (usually gear or plate) 13 driven in rotation by the shaft of the main pump. If the angle of the cylinder (tilt washer) of the ground the pump is controlled by steering, the auxiliary pump is also used to supply hydraulic fluid under pressure. The pressure in the pressure line of the auxiliary pump is supported overflow valve 10. This highway two make-up valve 9 is connected to a pipeline linking the main pump and motor. When the pressure in one of the pipelines below the value of the corresponding make-up valve opens and passes the pressurized fluid from the pressure line of the auxiliary pump for as long as the line does not restore the required level of pressure. After that, make-up valve by the pressure in the pipe is closed. Make-up valves must maintain such a minimum pressure in the pipelinenot to occur a cavitation in basic pump. To do this, set the required pressure in the pressure line of the auxiliary pump by adjusting the tension of the spring (set pressure) relief valve 10.

From the occurrence of excessively high pressure hydraulic lines are protected by two safety valves 8. During excessive rise in pressure in one of the pipelines can open a safety valve to leak into another pipeline with low pressure. In the discharge of the auxiliary pump also has a pressure relief valve 12, which protects the pump from pressure build-up clogging the filter 11.

Let’s note symbols of the hydraulic machines and hydraulic units in Fig. 1. Here P1...P2 - pumps, HM - hydraulic motor; CV1...CV2 - check valves;SV1...SV4 - safety valves, F - filter.

Before constructing a mathematical description of the power of the EHD surround regulation, form the design scheme, taking into account the following basic assumptions of[2, 8-10]:

1. Asynchronous motor 1 rotates shaft with angular velocity \( \Omega_n \), the value of which is independent power developed by the pump.

2. When operating hydraulic pressure in the pipelines4 do not reach the values for opening the safety valves 8.

3. Pressure \( p_{mv} \) in the line before the make-up valve is kept constant.

4. Efforts, overcome by hydraulic motor 5 in the management of object 7, may be represented by the sum of points given to the shaft of the motor inertia loads, load positioning and hydraulic friction.

5. Pipelines will take as short to allow them to neglect the inertia of the fluid and pressure loss due to friction.

The design scheme is shown in Fig. 2. In this circuit, the arrows show on the direction of fluid flow at the moment when the pressure is greater than the pressure \( p_1 \) and \( p_2 \).

![Fig. 2. The design scheme of the hydraulic power](image)

With all the above assumptions made obtaining a linear mathematical model of the power of the EHD with interior control prevents one essentially nonlinear characteristic that determines the dependence of flow and recharge \( Q_1 \) and \( Q_2 \) through the make-up valve from the pressures \( p_1 \) and \( p_2 \) in the pipelines. If the pressure in the pipe is below the supply pressure \( p_{up} \), the make-up valves, small changes can apply pressure ratio:

\[
Q_1 = k_{sv1}(p_r - p_1) \tag{1}
\]

\[
Q_2 = k_{sv2}(p_r - p_2) \tag{2}
\]

where: \( k_{sv} \) – the conductivity of makeup valve [2, 15-17].

If the pressure in the pipeline exceeds the charge pressure \( p_{up} \), the:

\[
Q_1=Q_{up}=0, \tag{3}
\]

as make-up valves are closed by the pressure in the pipelines.

At steady state hydraulic drive, for which the unloaded motor shaft does not rotate, the pressure in the pipes due to leakage of fluid from the pump and motor and final values of the conductivity of valves installed below the \( p_c \). With fluctuations in each pipeline after a certain make-up valve on one half cycle at low pressure enters the amount of fluid is compensated not only leaks, but the compressibility of the liquid. In the next half-cycle
of the compression of large volume of fluid in the pipe happens, which leads to an increase in its pressure. Flow of fluid through the make-up in the hydraulic valves is accompanied by increase in the average for the period of pressure fluctuations in the system or in increased levels of pressure in them. The amount of fluid received in the pipelines for the period of oscillation depends on the amplitude of fluctuations in pressure \( p_1 \) and \( p_2 \), so the average for the period of the valve conductance amplitude pressure in the pipes.

In the study of the dynamics of the hydraulic drive with small deviations of the variables from the steady-state values the level of pressure in the lines can be adopted under \( p_r \) pressure, so is permissible to use the linear relationship (1, 2). In the study of the dynamics of the hydraulic drive with large changes of variables have to take into account the non-linear characteristics of make-up valves.

For the time, when a small deviation of the cylinder (or the clone disk) from the equilibrium the pump delivers fluid through the pipeline to the pressure \( p_r \) and sucks fluid from the pipeline to the pressure \( p_2 \), the flow equation can be written using the D. Popov’s approach [2, 9], as follows:

for pipeline pressure \( p_1 \) pump flow:

\[
Q_p = Q_m + Q_{cp} + Q_{cm} + Q_{cp1} + Q_{cm1} + Q_{c1} - Q_r; 
\]

(4)

for a pipeline with pump flow pressure \( p_2 \):

\[
Q_p = Q_m - Q_{cp} - Q_{cm} - Q_{cp2} - Q_{cm2} + Q_{r1} - Q_{r2}. 
\]

(5)

In equations (4) and (5) the costs \( Q_{j} \) and \( Q_{2} \) are the components of the distribution moves that are associated with the compensation of compressibility. The remaining components designated in accordance with the design scheme (Fig. 2). To simplify expressions, determining the coefficients in the following equations, we consider the pump and motor hydraulic machines of the same type, such as axial piston, differing only in the fact that the pump is regulated by the angle cylinder (or disk) is not regulated. In this case, you can take:

\[
Q_{cp} = Q_{cm} = Q_{o}; 
\]

\[
Q_{cp1} = Q_{cm1} = Q_{o1}; 
\]

\[
Q_{cp2} = Q_{cm2} = Q_{o2}. 
\]

Given these relations, we define the components of the pump flow in the form of

\[
Q_m = \frac{q_m \Omega_m}{2 \pi}, 
\]

\[
Q_o = k_o (p_1 - p_2), 
\]

\[
Q_o = k_o p_1, 
\]

\[
Q_o = k_o p_2, 
\]

where: \( q_m \) – working volume of the hydraulic motor; \( \Omega_m \) – motor shaft angular velocity; \( \alpha \) – the angle of rotation of the shaft motor; \( k_o \) – conductivity slits through which

the pump and drive have a transmission of the fluid from the high pressure in the cavity with a low pressure; \( k_f \) – the conductivity of the slits, which the leakage of fluid from the pump and motor.

Costs \( Q_{j} \) and \( Q_{2} \) determined by the ratio (1) and (2), and the costs \( Q_{o1} \) and \( Q_{o2} \) assuming the pipes is hard to find the following relationships [2, 19, 20]:

\[
Q_{o1} = \frac{W_0 dp_1}{E_f \ dt}; 
\]

\[
Q_{o2} = \frac{W_0 dp_2}{E_f \ dt}; 
\]

(10)

(11)

where: \( W_0 \) – the internal volume of the pipeline with the connected volume of the cavity pump and motor; \( E_f \) – bulk modulus of the working fluid.

Substitute the components of the costs according to (1, 2, 6-11) in equation (4, 5). Then add these equations and transform:

\[
Q_p = \frac{q_p}{2 \pi} \Omega_p, 
\]

(12)

ideal pump flow \( Q_p \) in the form depending on the angle of inclination \( \gamma \) of cylinder blocks or angle swash plate pump:

\[
Q_p = \frac{q_p}{2 \pi} \Omega_p, 
\]

where: \( q_p \) - the pump displacement.

For axial piston pump:

\[
q_p = F_p z_p D_p g \Omega_p, 
\]

(14)

where: \( F_p \) – the working area of one piston (plunger) pump; \( z_p \) – the number of pistons; \( D_p \) – the diameter of the circle on which the axis of the piston pump.

As can be seen, the function is nonlinear. For small deviations of cylinder blocks (spacers) of the pump from the neutral position of the specified function can be linearized, and the equation (14) is written in the form:

\[
Q_p = k_{Q} \Omega_p, 
\]

(15)

where:

\[
k_{Q} = \frac{\partial Q_p}{\partial \Omega_p}. 
\]

For axial piston pump:

\[
k_{Q} = \frac{F_p z_p D_p \Omega_p}{2 \pi}. 
\]
where:

\[ k_{\text{m}} = k_{1} + 2k_{\text{w}} + \frac{k_{\text{w}}}{2}, \]

\[ p_{m} = \rho_{1} - \rho_{2}. \]

In equation (16), except for the input and output values \( \gamma \) and \( \alpha \), found of changing the time differential pressure \( p_{m} \), which is dependent on hydro-motor overcomes the load. When the inertial load value \( p_{m} \) determined torque \( M_{m} \), which is included in the equation of the rotational movement of the shaft motor:

\[ M_{m} - M_{\text{mplt}} - M_{\text{mpt}} - M_{\text{pco}} = J \frac{d^{2}\alpha}{dt^{2}}. \]

where: \( J \) – moment of inertia of the rotating parts of the motor to the shaft (given moment of inertia of the load and the rotor motor). In the future, this value will be called reduced moment of inertia motor.

Torque for the bulk hydraulic [6-8] is defined by the relation:

\[ M_{m} = \frac{q_{m}}{2\pi k_{q_{l}}} p_{m}. \]  

Friction torque \( M_{\text{mplt}} \) is created by friction in the motor. In general, the friction in the hydraulic motor can be mixed. To simplify the mathematical model of hydrodrive we will consider only the hydraulic friction [9, 10], setting:

\[ M_{\text{mplt}} = k_{\text{mplt}} \frac{dx_{l}}{dt}, \]

where: \( k_{\text{mplt}} \) is calculated from the slope of the approximating performance \( M_{\text{mplt}} = M_{\text{mplt}}(Q_{m}) \).

Friction torque \( M_{\text{mpt}} \) arising due to the friction of the load, consider the analogous dependence:

\[ M_{\text{mpt}} = k_{\text{mpt}} \frac{dx_{t}}{dt}. \]

Moment due to the positional load:

\[ M_{\text{pco}} = k_{\text{pco}} \alpha, \]

where: \( k_{\text{pco}} \) – the rigidity of positional load.

Using (19-22), from (18) that

\[ \frac{2\pi J}{q_{m}} \frac{d^{2}\alpha}{dt^{2}} = \frac{2k_{\text{mplt}}}{q_{m}} \frac{dx_{l}}{dt} + \frac{2k_{\text{mpt}}}{q_{m}} \alpha = p_{m}. \]

where: \( k_{\text{mplt}} = k_{\text{mplt}} + k_{\text{mpt}} \).

Considering simultaneously the equations (16) and (23) we find:

\[ \frac{\pi W_{0}}{E_{f} q_{n} k_{l}} \frac{d^{3}\alpha}{dt^{3}} + \left( \frac{\pi k_{\text{mplt}} W_{0}}{E_{f} q_{n} k_{l}} + \frac{2\pi k_{\text{mpt}}}{q_{n}} \right) \frac{d^{2}\alpha}{dt^{2}} + \frac{q_{n}}{2\pi k_{q_{l}}} \frac{2n^{2} k_{\text{pco}} W_{0}}{E_{f} q_{n} k_{l}} \frac{dx_{t}}{dt} + \frac{2n k_{\text{pco}}}{q_{n}} = \rho_{m}. \]

In real hydrodrives usually:

\[ 1 + \frac{2\pi^{2} k_{\text{mplt}} W_{0}}{E_{f} q_{m}} + \frac{4\pi^{2} k_{\text{mpt}}}{q_{m}} = 1. \]

Therefore, instead of (24) we have:

\[ \frac{\pi W_{0}}{E_{f} q_{n} k_{l}} \frac{d^{3}\alpha}{dt^{3}} + \left( \frac{\pi k_{\text{mplt}} W_{0}}{E_{f} q_{n} k_{l}} + \frac{2\pi k_{\text{mpt}}}{q_{n}} \right) \frac{d^{2}\alpha}{dt^{2}} + \frac{q_{n}}{2\pi k_{q_{l}}} \frac{2n^{2} k_{\text{pco}} W_{0}}{E_{f} q_{n} k_{l}} \frac{dx_{t}}{dt} + \frac{2n k_{\text{pco}}}{q_{n}} = \gamma. \]

\[ T_{\text{hd}} = \frac{q_{m}}{2\pi k_{q_{l}}}. \]

\[ T_{\text{ml}} = \frac{2\pi J W_{0}}{q_{m} E_{f}}. \]

the relative damping motor:

\[ \zeta = \frac{\pi(2E_{f} k_{\text{mplt}} + k_{\text{mpt}} W_{0})}{2J W_{0} E_{f} q_{m}}. \]

factor own feedback:

\[ k_{\text{pco}} = \frac{2n^{2} k_{\text{pco}}}{q_{n}}. \]

As can be seen from this expression, the coefficient of its own feedback part of the hydraulic power unit due to the combined action of hydraulic positional load and no-leak of hydraulic machines.

Given the input parameters (26) the Laplace transform [14, 18] to the form:

\[ T_{\text{hd}}(s) \frac{s^{2}}{s^{2} + 2\zeta_{m} \frac{s}{s} + 1} K(s) = \gamma(s) - k_{\text{pco}} \alpha(s). \]

Block diagram of the power part of EHD according to equation (31) are shown in Fig. 3.

Fig. 3. Block diagram of the power part of EGP

In the absence of positional load (22) or seals for hydraulic, or insignificant moment of the forces positional load and high hydraulic leak (which is usually the case in practice) coefficient of the own feedback is negligible. It should be noted that this ratio in the event of significant influence can be included in the external feedback EHD.

Then, a block diagram of the power of the drive will be as shown in Fig. 4. This scheme is, in fact, reflects the transfer of the control signal - the angle to clone the cylinder (or puck) \( \gamma \) - and its influence on the output signal - the angle of rotation of the shaft motor \( \alpha \).
In the future, consider the block diagram of the power part of EHD with the volume control as shown in Fig. 4. According to this block diagram is obtained for the transfer function of the angle of rotation of the drive motor shaft angle $\alpha$ on the cylinder (or puck) $\gamma$:

$$W_{\alpha}(s) = \frac{\alpha(s)}{\gamma(s)} = \frac{1}{T_{hd}(s) + 2\zeta_m T_{sd} s + 1}.$$  \(32\)

CONCLUSIONS

Thus, on the basis of the research the following conclusions:

1. The mathematical model of the dynamic characteristics of the power unit of automatic electrohydraulic drive with volume regulation is developed. The block diagram of the control signalis presented.

2. Transfer functions for the drive output shaft angle motor with control signal (the slope of the cylinder or disk) is received.

МАТЕМАТИЧЕСКАЯ МОДЕЛЬ ЭЛЕКТРОГИДРАВЛИЧЕСКОГО ПРИВОДА С ОБЪЕМНЫМ РЕГУЛИРОВАНИЕМ

Соколов В.И., Кроль О.С., Степанова О.Г.

Аннотация. Рассмотрен электро-гидравлический привод с объемным регулированием. Силовая часть привода включает объемный насос с регулируемой подачей, вспомогательные устройства и исполнительный гидродвигатель объемного типа. В гидроприводе применяется аксиально-поршневой насос, подача которого регулируется изменением угла наклона блока цилиндров или изменением угла наклона шайбы. В качестве исполнительного гидродвигателя используются аксиально-поршневой или радиально-поршневой гидромотор. В гидроприводе установлены вспомогательные устройства: клапаны, фильтр, насос и бак системы для подпитки рабочей жидкостью силовой части привода. От возникновения чрезмерно высокого давления трубопроводы гидропривода защищены двумя предохранительными клапанами. В линии нагнетания вспомогательного насоса также имеется предохранительный клапан, который защищает насос от повышения давления при засорении фильтра.

При разработке математической модели сделаны следующие основные допущения: асинхронный электродвигатель вращает вал насоса с угловой скоростью, величина которой не зависит
мощности, развиваемой насосом; при работе гидропривода давления в трубопроводах не достигают значений, при которых открываются предохранительные клапаны; давление в магистрали перед подпиточным клапаном поддерживается постоянным; усилия, преодолеваемые гидромотором при управлении объектом, представлены суммой моментов от действия приведенных к валу гидромотора инерционной нагрузки, позиционной нагрузки и гидравлического трения; трубопроводы принимаются настолько короткими, чтобы можно было в них пренебрегать инерцией жидкости и потерями давления из-за сопротивления трения.

Разработана математическая модель динамических характеристик силовой части автоматического электрогидравлического привода с объемным регулированием. Представлена структурная схема передачи управляющего сигнала. Получена передаточная функция привода.

**Ключевые слова:** математическая модель, насос, гидромотор, давление, расход, объемное регулирование, структурная схема, передаточная функция.
